

Review on *Doliops* Waterhouse, 1841 (Coleoptera: Cerambycidae) of Mindanao, Philippines with description of a new species

Analyn Anzano Cabras, Arvīds Barševskis

Cabras A. A., Barševskis A. 2016. Review on *Doliops* Waterhouse, 1841 (Coleoptera: Cerambycidae) of Mindanao, Philippines with description of a new species. *Baltic J. Coleopterol.*, 16(2): 143 - 156.

A new species, *D. coritioi* sp. n. is described and illustrated from Mt. Kiamo, Malaybalay, Bukidnon, Mindanao Island, the Philippines, which is the twelve *Doliops* species described from Bukidnon. New species is distinguished from its allied species by its unique elytral markings. The genus *Doliops* is now represented by 55 described species. The article contains a bibliography and photos of all species of this genus, distributed in Mindanao Island.

Keywords: *Doliops*, checklist, new species, Cerambycidae, endemic, taxonomy

INTRODUCTION

The Philippines is one of 17 mega-diverse countries in the world with a level of endemism believed to be ten times of Galapagos Island (Heaney, 1998). Among the taxa in the country with a high level of endemicity are insects with 70% endemism and currently has 22,000 described species. Among the most numerous insect group with an estimated 7,000 species in the Philippines are the order coleoptera (Baltazar 2001).

The Philippine coleoptera with a 79% endemism is still poorly known although some taxon are

well studied. Coleoptera are generally polyphagous but most are associated with specific plants and forest habitats thus the accelerated decline of forest habitats in the Philippines is a major threat especially to the coleoptera species with specific host and food plants (Cassola 2000). The genus *Doliops* belonging to the tribe Apomycini is one of the rare beetle species highly associated with forest habitats and with more than 95% of endemism. Currently, it has 55 known species and almost exclusively distributed in Philippines islands (Barševskis 2014). Most species are rare in collections or known only by type specimens (Barševskis & Jaeger, 2014). This genus *Doliops* has been extensively studied with

new species described yearly by Vives and Barševskis (Barševskis 2015).

The distribution of *Doliops* in the Philippines is as follows: Luzon has 26 spp., Mindanao has 18 spp., Samar Island has 3, Mindoro and Negros Island has 2, Babuyan, Calayan, Basilan, Bucas Grande, Masbate, Polillo, Bohol and Siargao has 1 species (Barševskis 2015). Mindanao Island which is the second biggest island in the Philippines (94,630 km²) is a home to 18 species of *Doliops*. During the last Pleistocene epoch it is believed to be connected with land bridges to Samar, Leyte and Bohol thus the term Greater Mindanao. Dickerson (1928) divided Mindanao into 4 faunal and floristic subregion namely Eastern Mindanao-Samar-Leyte, Bukidnon highlands, Cotabato and Zamboanga. The different subregions of Mindanao have different species affinity and have unique flora (Vallejo 2011). The unique flora of each subregion impacts the faunal composition especially the phytophagous species including coleoptera with unique host and food plants. In this paper, a checklist of the *Doliops* from Mindanao together with their distribution and a description of another species from Malaybalay, Bukidnon is presented.

MATERIAL AND METHODS

The type material of the new species described herein is deposited at Central Mindanao Zoological Museum - CMZM. Morphological features were observed under Luxeo 4D stereoscopic microscope. Photographs of the holotype female was taken with a Nikon D5300 digital camera.

RESULTS AND DISCUSSION

Doliops coriticoi sp.n.

(Fig.1)

Type material. Holotype: Female. Philippines: Mindanao, Mt. Kiamo, Bukidnon, 01.05.2015, local collector leg (CMZM)

Description. Body black and shiny without metallic luster. Surface with spots of pale yellow and green scales. Length: 13 mm, Width: 6.4 mm.

Head black, finely punctate shiny; head with longitudinal median band of pale yellow and green scales between eyes and antennal bases. Genae under the eyes with oblique band of pale yellow and green scales. Labrum covered with numerous setae. First antennomere black, shiny and pubescent, without metallic luster. Basal half of the second antennomere brown with white pubescence; apical half of the second antennomere black with black pubescence and scarce setae. Basal half of the 3rd antennomere pubescent with white setae, apical half brown to black pubescent with scattered long black setae. Antennomere segments 4-8 brown with white and brown pubescence and few scattered black setae. Antennomere 9-10 black and with pubescence.

Pronotum convex, finely and sparsely punctured especially the lateral side. Black and shiny with the pattern of pale yellow and turquoise elongated diamond shaped scales. One thin band from the base up to three fourths of the pronotum, and short thin band in the lateral side of the basal margin, which towards the apical margin forming a half circle band.

Scutellum rounded and tomentose apically.

Elytra convex, black and shiny, and heavily punctured with four medium sized circular spots located basally on either side of scutellum. Two are located dorsally and another two laterally. Additional two thin transverse bands and tear shaped apical stripe. Second transverse band on apical 1/3 is in zigzag form and confluent at the middle to the first transverse band as well as the tear shaped apical stripe. Bands are thin with diamond shaped pale yellow and green scales with few scattered orange scales. Apical tear shaped stripe confluent to the second transverse band. Elytra finely punctate and tomentose. In basal part with sparse and coarse punctuation and tomentose. Width of elytra at shoulders: 5.0 mm.

Fig.1. A-C. *Doliops coriticoi* sp.n. (dorsal, ventral and lateral)

Largest width of elytra behind the middle: 6.8 mm.

Femora with light yellow apical spots and more or less tomentose. Surface of tarsomeres covered with white tomentum with sparse black setae. Tibia and tarsi apically covered with numerous setae, tomentose. Underside has the following markings of pale yellow and green scales: large C-shape patch on each side of metasternum; irregular band at each side along apical margin of ventrite I; a small patch on each side of ventrites II–IV, and a tiny spot on ventrite V.

Distribution: Mt. Kiamo, Malaybalay, Bukidnon (Fig. 2)

Differential diagnosis: New species is similar to *Doliops bukidnoni*, but with different pattern on basal part of elytra, i.e. monochrome black with

two circles of green scales, one laterally, and the other dorsally, while in *D. bukidnoni* basal part of elytra with green bands (Fig. 3).

Etymology. This species is named after botanist friend of first author Fulgent Coritico of Central Mindanao University who obtained the specimen for description and in appreciation of his contribution in the advancement of botanical works in different mountains in Mindanao including Mt. Kiamo.

Photo: Fig. 20

The first species of *Doliops* described from Mindanao was *D. curculionoides* Waterhouse, 1841 followed by *D. geometrica* Waterhouse, 1842 which was described a year later. Four species of *Doliops* were described in the 20th century by known coleopterists such as Waterhouse, Heller, Schultze and Kriesche (Barševskis 2015). For nearly a century *Doliops* study in Mindanao has been dormant until Vives (2009) described *D. edithae* from the materials submitted by Mr. Estan Cabigas. Since then, 12 species of total *Doliops* diversity in Mindanao have been described almost yearly (Vives 2012a, 2012b, 2013a, 2013b, Barševskis 2013, 2014, Barševskis & Jaeger 2014).

Of the 19 *Doliops* species found in Mindanao, 15 are endemic to Mindanao, 2 are Greater Mindanao endemic and another 2 species are Philippine endemic. Due to limited field collections, actual distribution and endemism of the *Doliops* species is not conclusive. However, pre-

vious collections would tell that they have a restricted distribution often confined to one mountain or locality. Of the 19 species, 12 are recorded from the highlands of Bukidnon while 6 are recorded from Mt. Apo Natural Park. Other localities with records of *Doliops* are South Cotabato, Sarangani, Surigao del Sur, and Agusan del Sur. Furthermore, 10 species of *Doliops* were found in only one locality either in Bukidnon or Mt. Apo. Future field expeditions would confirm if these species are site endemic to the province where they were collected.

Based on the biogeographic subregions of Mindanao as proposed by Dickerson (1928), Bukidnon highlands have the highest species richness, followed by Mt. Apo which borders Eastern Mindanao and Cotabato. The distribution pattern of *Doliops* is very similar with the distribution pattern to the genera *Pachyrynchus* and *Metapocytus* (Curculionidae: Entiminae: Pachyrynchini) which is believed to whom this group is mimicking. In his article "Monograph of Pachyrynchini...", Schultze (1923) mentioned that the center of distribution of Pachyrynchini in Mindanao are Bukidnon and Mt. Apo. A similar pattern was observed with *Doliops* where half of the described species are from the Bukidnon highlands and Mt. Apo while a few are from South Cotabato, Surigao and Agusan (Vives 2005, Barševskis 2014, 2015).

The high association of *Doliops* with *Pachyrynchus* which are generally forest dweller (Cabras et al. 2016, Linsley 1959, Schultze 1923) indicate that these species are associated with forest habitats and are among the most at risk of habitat degradation due to deforestation. Their rarity and sporadic distribution plus habitat degradation and the rampant illegal poaching of these species as evident in different online stores selling specimens require immediate attention. Since most species were only described from one or few collected specimens, no ecologic data or abundance data is available for these species. Conservation efforts should be immediately conducted especially to the rare and site endemic species before extinction catches up.

CONCLUSION AND RECOMMENDATION

Doliops coriticoi sp. n. is the twelve *Doliops* species discovered from the highlands of Bukidnon and the sixth species new to science from Mt. Kiamo, Malaybalay, Bukidnon. *Doliops* of Mindanao comprises 33.96% of the species found in the Philippines. The highlands of Bukidnon and Mt. Apo Natural Park are the center of distribution of *Doliops* in Mindanao. These are also the same centre of distribution of the Pachyrychnini which is believed to whom this group is mimicking. These two areas alone have 17 out of the 18 *Doliops* species in Mindanao. More ecologic and faunistic work should be done on the genus *Doliops* especially in unexplored mountains which may hoard new species or new records. Conservation efforts should be conducted especially to the noted site endemic species. Mt. Kiamo should also be listed as a protected area in order to conserve the endemic and threatened species found in this mountain ecosystem.

ACKNOWLEDGEMENT

We would like to thank Fulgent Coritico for acquiring the specimens for identification and the local villagers of Mt. Kiamo for the help in obtaining the specimen used in the description. A great thanks also to the University of Mindanao Research and Publication Center for the continuous support in the first author's research endeavours. The authors would also like to thank Geonzyl Alveola for helping in the preparation of the photographs. We wish to express our gratitude to Dr. Alexander Anichtchenko and Dr. Alexey Shavrin for valuable comments and suggestions on the manuscript of this article. We thank Dr. Alexander Anichtchenko for help in preparation of the photographs of the species of the genus *Doliops* (except new species).
